

Table [climate-associated cluster candidates]. Putative climate-associated LD clusters across BayPass configurations.

Population set	Ω (covariance)	Axis	Candidates (≥ 5)	Candidates (≥ 10)	Median size (markers)
Åland-excluded (19 populations)	Internal (full data)	PC1	14	8	88
		PC2	16	9	253
	LD-pruned (fixed) [primary]	PC1	9	3	126
		PC2	24	14	101
Full (20 populations)	Internal (full data)	PC1	7	6	497
		PC2	44	28	98
	LD-pruned (fixed)	PC1	4	3	449
		PC2	16	11	260

A cluster is a putative candidate when at least 5 (or 10) of its member markers reach $\text{BF(dB)} \geq 15$. Genome-wide median cluster size = 9 markers (32,854 clusters with a consensus genotype); the excess size of candidate clusters over this median reflects the size dependence of the member-count criterion. The eMLG gate restricts this set to clusters that track climate as a unit (per-cluster table).
