

Table [climate-associated cluster candidates]. Putative climate-associated LD clusters across BayPass configurations.

Population set	Ω (covariance)	Axis	Candidates (≥ 5)	Candidates (≥ 10)	Median size (markers)
Åland-excluded (19 populations)	Internal (full data)	PC1	14	7	68
		PC2	16	7	116
	LD-pruned (fixed) [primary]	PC1	16	10	68
		PC2	21	8	118
Full (20 populations)	Internal (full data)	PC1	9	5	272
		PC2	43	24	94
	LD-pruned (fixed)	PC1	7	5	486
		PC2	53	36	89

A cluster is a putative candidate when at least 5 (or 10) of its member markers reach $\text{BF(dB)} \geq 15$. Genome-wide median cluster size = 9 markers (32,840 clusters with a consensus genotype); the excess size of candidate clusters over this median reflects the size dependence of the member-count criterion. The eMLG gate restricts this set to clusters that track climate as a unit (per-cluster table).
